Standard Operating Procedure #7
Title: Large Animal Branding, Ear Tagging and Microchip Implanting

Background:
Individual animal identification is essential for proper management of all agricultural animals used in research and teaching at Washington State University (WSU) including cattle, horses, swine, sheep, goats and camelids.

IACUC requirements
All methods listed below for identification must be outlined and approved on the Animal Subject Approval Form (ASAF) before implementation of its use. PI's may refer to this SOP in the ASAF for details of the procedures. All personnel performing anyone of these procedures should be trained by someone who is proficient at the procedure and training should be documented.

Monitoring of animals after Livestock Branding, Ear Tagging, Microchip implanting
- All animals will be observed during the daily check.
- Personnel performing the procedures will be trained to conduct the restraint and process associated with the branding or tagging.
- New personnel performing the procedures will be under the direct supervision of experienced Facilities Manager.

Permanent identification is also an essential aspect of the cattle industry as legal proof of ownership, and branding of cattle is recognized as viable option. Numerous studies (Lay et al., 1992, Schwartzkopf-Genwwein, 1997) assessed pain and behavioral response to hot iron branding vs. freeze branding and have concluded that freeze branding offers a permanent form of identification that is easy to read, causes minimal damage to the hide and is less painful than hot branding. Thus freeze branding is the only method of branding acceptable at WSU.

Freeze Branding
Species: Cattle, Horses

Background:
When super-cold or chilled (-100°F to 300°F) special branding irons are applied to the hide of the animal, the pigment-producing cells in the hair follicle are destroyed or altered. The first day after branding the skin swells producing a welt. In two to three weeks, the brand will form a scab and peel. Six to eight weeks after branding, healthy unpigmented hair (white in color) will replace the scab.

Equipment and Materials needed:
Personal Protective Equipment
Insulated safety gloves and face shield must be worn by the personnel performing the procedure.

Inspection of instruments
All instruments i.e., brass freeze brand irons, electric clippers, safety razor, alcohol, gauze, liquid nitrogen container, Styrofoam cooler, and squeeze chutes should be inspected prior to use and ensure that they are in safe working order.
**Freeze-branding irons**
Brandling irons should be heavy copper or bronze with slightly rounded faces. They should be 3- to 4-inch irons, 3/8- to 1/2-inch thick and at least 1 inch deep.

**Coolants:**
Dry ice and alcohol are the most commonly used coolants. The alcohol must be denatured and at least 95 percent alcohol. Less pure forms of alcohol contain too much water and will not cool the irons properly. A minimum of 10 pounds of dry ice is usually needed to cool irons along with 3-5 gallons of alcohol to brand 20-30 animals.

Liquid Nitrogen can also be used as a coolant, but because it is colder, you must take care not to leave the irons on the animal too long. Refer to the Table below.

**Container for coolant**
The container should be insulated to keep the solution as cold as possible. Use two metal containers, one set inside the other with an insulating compound between, or a bucket wrapped in insulation. Styrofoam coolers are excellent, but should be set inside another container because they are fragile and easily broken. Select a container large enough to accommodate all the irons needed.

**Clippers**
Clip the hair closely before branding. The cutters and combs should be sharp, with extra blades available to replace dull or damaged ones.

**Brush and plastic squirt bottle**
A stiff bristle brush is handy for brushing away loose hair and removing skin scurf after the animal has been clipped. A squeeze bottle is helpful for applying alcohol to the clipped area. A 20 oz plastic bottle with a 1/8” hole in the lid works well also.

**Restraining equipment**
The animal must be securely restrained in a squeeze chute or head gate. Calves may be restrained on the ground on their sides.

**Chilling the irons**
When dry ice is added to alcohol, it will bubble profusely. As the solution is cooled, it will reach a steady rate of bubbling. The alcohol or liquid nitrogen should cover the head of iron by at least one inch. Cool irons for 20 minutes before using them on the first animal. After the irons have been used in branding, they should be put back in the solution immediately if they are to be used again. It will take at least 2 minutes for them to reach minimum temperature again.

**Length of time for iron application**

<table>
<thead>
<tr>

<tr>
<td>Over 18 months</td>
<td>45-50</td>
</tr>
<tr>
<td>Mature animals with thick hide (i.e. Hereford)</td>
<td>50-60</td>
</tr>
</tbody>
</table>
**Step-by-step branding**

Step 1. Cool irons as listed above

Step 2. Restrain the animal in head gate or squeeze chute, clip the area selected to brand. After clipping, brush away loose hair and any scurf that is on the skin.

Step 3. Saturate the branding area with alcohol. You may need a brush to work the alcohol all the way to the skin.

Step 4. Immediately after you have applied the alcohol solution, apply the branding iron to the hide. Apply very firm pressure to the iron. Hold the iron on the area and don't let it slip. Rocking the iron gently from top to bottom and side to side will make a better brand. Have an assistant keep track of the time so the branding irons are in place for the desired length of time.

Step 5: Remove the iron from the animal and immediately place the iron in the coolant for additional branding.

A good brand will show up as indented on the animal after branding, and after a few minutes will swell and create a raised version of the brand.

**Pain Relief Recommendation**

The AVMA guideline on branding, recommends for best practice to use pain relief with freeze branding. A topical anesthetic such as lidocaine or systemic analgesics such as Flunixin would be options.

**Ear Tagging**

**Type:** Radio Frequency Identity Tags (R-FID button), silver and plastic tags  
**Species:** Cattle, Swine, Sheep, Goats, Llamas, Alpacas, and other Camelids, Bighorn sheep, Captive Deer

**Equipment and Materials needed:**

**Personal Protective Equipment**
Clean examination gloves are recommended for personnel performing the procedure.

**Inspection of instruments**
Squeeze chutes, halters, nose tongs, tag applicator and tags should be inspected prior to use to ensure that they are in safe working order.

**Ear tags**
Please see USDA APHIS website for listing of Official Ear tags:  

**Step-by-step tagging**

Step 1: Adult animals should be restrained in the squeeze chute just long enough to perform the procedure

Step 2:. The head should be haltered or nose tongs applied to prevent injuries to the animal or attendants. The ears should be cleaned with betadine or alcohol and hair clipped if necessary. The numbered tags with special applicators may be applied on one or two ears.

Step 3: The tags are inserted in to the outer portion of the ear avoiding the outer cartilage supporting the ear.
Microchip implanting
Type: Microchip
Species (example): Large animals

Background:
The USDA published a final rule in 2013 establishing regulations regarding the traceability of U.S. livestock moving interstate. One of the permitted methods of identification is a 15 digit microchip that begins with the designated US prefix 840. WSU also recognizes microchips as a permanent form of individual identification in numerous species.

Equipment needed
Personal Protective Equipment
Clean examination gloves.

Inspection of instruments
Microchip frequencies include: 125 kHz, 128 kHz and 134.2 kHz. Ensure that your scanner will read your microchip before implanting, and understand what type of microchip you need for your particular species. Microchips come in sterile, individual injectors that look like a large syringe and needle and are sealed.

Implant location
Cattle, camels, sheep and goats: can be microchipped behind the left ear as a subcutaneous injection or in the tail web for goats and sheep. Large carnivores can be implanted similar to a dog or cat in the subcutaneous tissue of the neck between the shoulder blades.

Horses typically are microchipped in the nuchal ligament on the left side halfway between the poll and the withers approximately one inch below the midline of the mane, only after a clip and surgical scrub of the area.

Step-by-step Microchip
Step 1: Restrain an adult animal in a squeeze shoot, or halter. In special cases an animal may need to be sedated for implantation.

Step 2: Clean area well or clip and scrub based on species.
Step 3: Insert the needle under the skin or into the nuchal ligament, depress plunger, pinch the skin where the needle went in and pull the needle out ensuring that the microchip stays under the skin.
